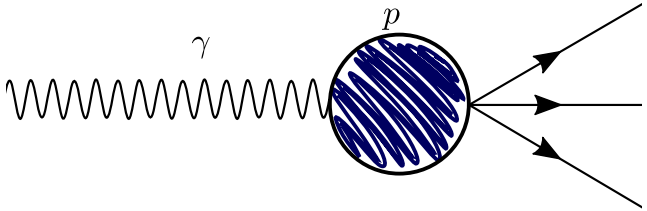
Setting the scene

The Standard Model of Particle Physics

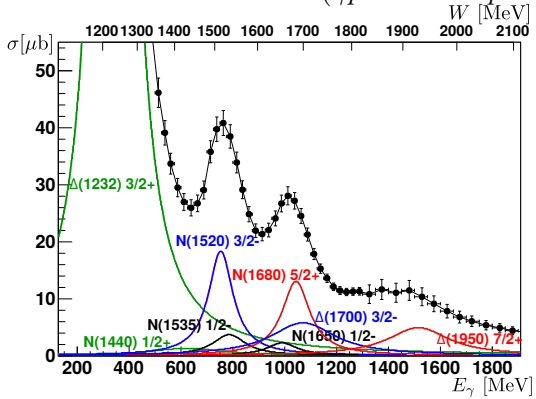
- matter consists of 12 (anti-)*fermions*
- quarks interact via *strong interaction*
- form bound states: mesons ($q\bar{q}$) and baryons (qqq)

baryon spectroscopy (photoproduction) gives insight in strong interaction



Setting the scene

Observe resonances R^* in the cross sections $\sigma(\gamma p \to R^* \to pM)$



Total cross section $\sigma(\gamma p \to R^* \to p\pi^0)$ [Wunderlich et al. 2017]

→goal: (help to) identify contributing resonances as strong bound states!

1. Theoretical Basics

2. Experimental Setup

3. Preliminary results

4. Conclusion

1. Theoretical Basics

2. Experimental Setup

3. Preliminary results

4. Conclusion

Theoretical Basics

Unpolarized differential cross section

$$\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega} = \frac{1}{4}\rho \sum_{\text{spins}} |\, \langle f|\mathcal{F}|i\rangle \,|^2,$$

where

$$\mathcal{F} = i(\vec{\sigma}\cdot\vec{\epsilon})F_1 + (\vec{\sigma}\cdot\hat{q})(\vec{\sigma}\cdot(\hat{k}\times\vec{\epsilon}))F_2 + i(\vec{\sigma}\cdot\hat{k})(\hat{q}\cdot\vec{\epsilon})F_3 + i(\vec{\sigma}\cdot\hat{q})(\hat{q}\cdot\vec{\epsilon})F_4$$

F_i : complex CGLN Amplitudes

[Chew et al. 1957]

$\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega} \in \mathbb{R}$, not sufficient do determine $\mathcal{F}$ unambiguously
$\rightarrow$ Polarization Observables

Theoretical Basics

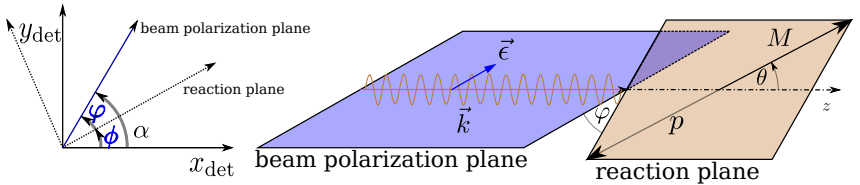
- resonances are broad, overlapping, require sophisticated analysis (PWA)
- constraints feeding the analysis can be derived from Polarization observables

Beam asymmetry $\boldsymbol{\Sigma}$

$$\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}(\varphi) = \frac{\mathrm{d}\sigma}{\mathrm{d}\Omega_0}\left[1 - p_\gamma^{\mathrm{lin}} \boldsymbol{\Sigma} \cos(2\varphi)\right]$$

polarization angle φ, polarization degree p_γ^{lin}

[Sandorfi et al. 2011]



Definition of the polarization angle

1. Theoretical Basics

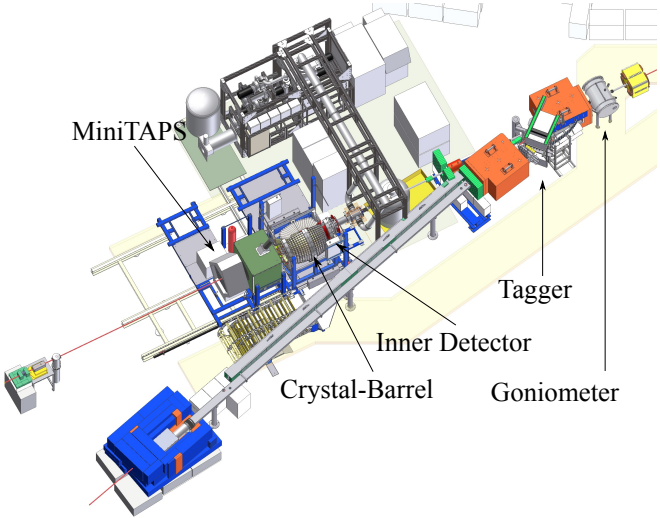
2. Experimental Setup

3. Preliminary results

4. Conclusion

Experimental setup

- generate photon beam from accelerated electrons via bremsstrahlung, with $E_\gamma \leq 3.2\,\mathrm{GeV}$
- photon beam impinges on liquid butanol target: $\gamma p \to pM \to pX$
- measure decay products X of different final states: $M = \pi^0/\eta/\eta'/\ldots$



Overview of the experimental area, adapted from [Walther 2022]

1. Theoretical Basics

2. Experimental Setup

3. Preliminary results

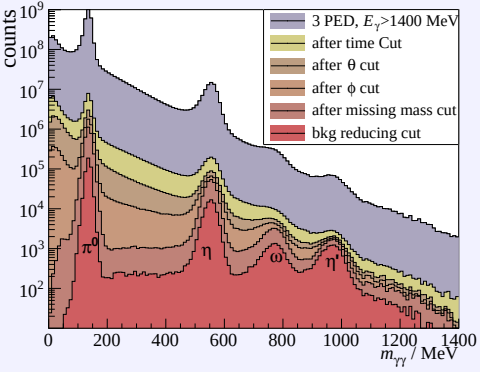
4. Conclusion

Preliminary results (η')

Event selection (η')

analysis performed in 2x6 bins of $(E_\gamma, \cos\theta_{\eta'}^{\mathrm{CMS}})$, $E_\gamma \in [1400, 1800]$ MeV

- 3 detector hits, 2 uncharged, 1 charged
- coincident detector hits
- kinematic cuts derived from energy-momentum conservation $p_\gamma + p_p = p'_p + p_{\eta'}$
- additional cuts to reduce background contributions

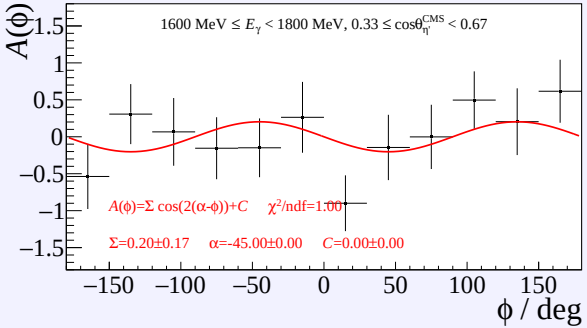


Preliminary results (η')

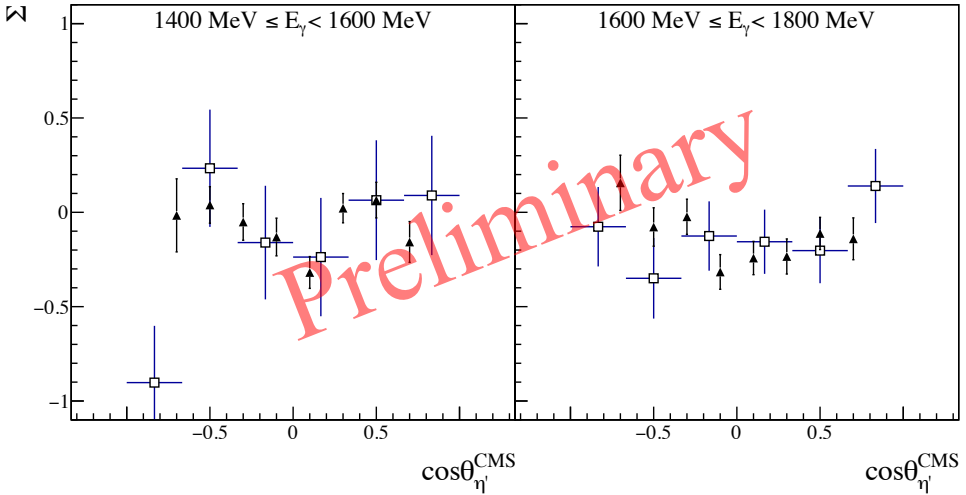
Method

- measure in 2 distinct orthogonal polarization settings $\perp, \parallel$
- χ^2-fit to event yield asymmetries

$$A(E_\gamma, \theta, \phi) = \frac{N^\perp(E_\gamma,\theta,\phi) - N^\parallel(E_\gamma,\theta,\phi)}{p_\gamma^\parallel N^\perp(E_\gamma,\theta,\phi) + p_\gamma^\perp N^\parallel(E_\gamma,\theta,\phi)} = \Sigma(E_\gamma,\theta)\cos\left(2\left(\alpha^\parallel - \phi\right)\right)$$



Preliminary results (η')



Beam asymmetry Σ for all energy and angular bins

Preliminary results (η)

Event selection (η)

analysis performed in 11x12 bins of $(E_\gamma, \cos\theta)$ by [Afzal et al. 2020]

Method

- fit to event yield asymmetries using BAYESIAN inference
- $p(\theta|y) \propto \mathcal{L}(\theta, y) \cdot \pi(\theta)$, obtained using MARKOV-CHAIN-MONTE-CARLO (MCMC)
